## ACKNOWLEDGMENTS

---

Partial funding for these small grain and legume performance evaluations was provided by Idaho wheat, barley, and grain legume producers through cooperative research and extension grants from the Idaho Wheat and Barley Commissions and the USA Pea and Lentil Council. Support was also provided by the Idaho Agricultural Experiment Station and the Cooperative Extension System of the University of Idaho. Fees paid by seed companies were also used to support the evaluations. This report represents the collective efforts of many individuals. The off-station nurseries were coordinated locally by County Educators with the Idaho Cooperative Extension System. Grower-cooperators provided their time, land and other inputs for management of these trials and appreciation is expressed to them for their support. The University of Idaho Wheat Quality Laboratory at Aberdeen determined the protein content and kernel hardness of harvested spring and winter wheat samples. Appreciation is also expressed to the numerous support workers who assisted with trial establishment, maintenance, harvest, and grain processing. Finally, cereal breeders throughout the Northwest are recognized for their contributions since the nurseries would not be possible without their entries. The author wishes to thank all who have contributed to the success of this project.

## **Introduction**

This report summarizes the performance of winter wheat, spring wheat, spring barley, winter pea, spring pea, lentil and chickpea cultivars tested in extension variety trials conducted in northern Idaho during the 2011-2012 crop season. The variety trials were located in cooperators' fields at 8 test sites in Lewis, Nez Perce, Latah, Benewah and Boundary counties.

Plant breeding and extension testing programs strive to increase yield potential through enhanced disease and insect resistance, winter hardiness, straw strength and other agronomic factors. In addition, varieties are developed for improved end-use quality and new markets. A more detailed description of variety development, cooperative extension testing and evaluation, and seed production programs is given in the University of Idaho publication CIS 976 titled, "Small Grain Variety Development and Adaptation in Idaho". Additional variety performance data for northern Idaho and the rest of the state can be viewed at the website <http://www.extension.uidaho.edu/cereals/>. In Idaho, public varieties are evaluated for general adaptation in regional testing programs. The northern Idaho Extension variety-testing program evaluates the relative performance of cereal and legume varieties grown in various northern Idaho environments under a range of commercial production conditions. Breeding lines that have shown promise through regional, public and private testing programs are evaluated along with leading commercially released varieties.

Increases in field crop yield are the result of a combination of improved agronomic practices and advances in variety development. Trials reported in this publication help producers compare new cultivars with widely grown cultivars using field production practices common for their area. The information provided represents crop performance results from specific locations, production practices, and environmental conditions. Relative performance of varieties can change when tested under other environments and production practices. Evaluation of any variety included in these trials should not be construed as recommending any variety over varieties not included in the trials.

## **Cereal Test Procedures**

Thirteen winter cereal trials were planted in northern Idaho during the fall of 2011 and 10 spring cereal trials were planted in the spring of 2012. For each crop, the seeding rate for all entries was a common number of seeds planted per square foot. These rates were determined by weighing 300 seeds of each cereal cultivar. Winter wheat and spring barley were planted at 24 seeds per square foot, and spring wheat at 28 seeds per square foot. Winter wheat, spring wheat, and barley seed were treated with 1 ounce of Dividend Extreme per 100 pounds of seed. Plots in conventional tillage systems were planted 15 feet long on 5-foot centers with 7 rows, 7-inches apart. Direct-seeded trials had 5 paired rows with 3-inch spacing and 10-inch from center to center of pairs. Typical cereal seeding depth varied from 1 to 1.5 inches depending on soil texture and moisture conditions. All trials were replicated 3 or 4 times in complete randomized design (CRD) or a randomized complete block design (RCBD). After plants were well established, the plots were cut back to a plot size of approximately 11.5 feet in length with an application of glyphosate using a tractor-mounted, shielded sprayer. All trials were established and maintained primarily under "grower management" conditions. Fertilizers and pesticides used in the trials are listed in Table 1 for the sites where the information was reported. Planting and harvesting operations by University of Idaho personnel were timed to approximately coincide with the cooperator's operations.

Each small grain entry at each location was evaluated for grain yield, test weight, plant height, and lodging. Plot length was measured to determine each individual plot area. Cereal yields were reported in bushels per acre, using the standard 60 pounds per bushel conversion for wheat and 48 pounds per bushel for barley. Protein and kernel hardness were determined from a composite sample of three or four replications from each site for both winter and spring wheat. Wheat whole grain protein at 12% moisture was measured at the University of Idaho Wheat Quality Laboratory at Aberdeen using Near Infrared Spectrometry (NIRS) technology. Kernel hardness was also determined by NIRS. Values under 35 indicate soft wheat and values above 35 indicate hard wheat. Cereal test weight is reported in pounds per standard bushel. Cereal plant height is the length of the plant from the soil surface to the tip of the head (awns excluded).

Lodging was determined for all cereals. Area affected was scored from 0% to 100%, with 0% equal to no lodging and 100% being completely lodged. Percentage grain plumps and thins were measured for barley. Plumpness is the percent of the sample that stayed on top of a 6/64-inch slotted screen after shaking. Thin percentage is the portion of the sample that went through a 5.5/64-inch slotted screen.

### **Legume Test Procedures**

In the spring of 2012, spring pea and lentil trials were seeded near Craigmont, Genesee and Moscow. A chickpea trial was conducted at the University of Idaho's Kambitsch farm northwest of Genesee. For each legume cultivar, 100 seeds were weighed and seeding rates calculated to give a planting density of pea at 8 seeds per square foot, lentil at 9 seeds per square foot, and chickpea at 6 seeds per square foot. Spring pea and lentil seed were treated with 2 ounces of an Apron, Cruiser, and Maxim mix per 100 pounds of seed and chickpea seed was treated with 2.5 oz of "Garb mix" (Apron, Cruiser, Maxim and LSP) per 100 pounds of seed. Legume plots were established in a manner similar to the cereal trials; they were planted at 20 feet long and were cut back to 15 feet after establishment. Planting depths used were between 1 and 2 inches for lentils and between 1.5 and 2.5 inches for pea and chickpea. Sites were hand-weeded to supplement chemical control. Legumes were evaluated for seed yield, plant height, and 100-seed weight. Seed yields were expressed as pounds per acre. Lentil or chickpea plant heights or pea vine lengths were measured from soil surface to end of growing point on the main tiller. Pea canopy heights were measured from the soil surface to the average tall point in the canopy approximately three weeks prior to harvest.

### **Statistical Interpretation**

Crop class averages are shown within the body of the data tables and overall trial average is shown at the bottom of the table. The least significant difference (LSD) and the coefficient of variation (CV) are listed. The LSD is given at the 5% error level and is an aid in comparing varieties. If the measured values of any two varieties within a column differ by the LSD value or greater, they may be considered different with a confidence level of 95%. If the measured values are less than the LSD value, the differences may be due to random error rather than real differences. If no significant statistical differences were found among cultivars, NS is shown for the LSD. Where data represent cultivar means across locations, an approximation of combined LSD was calculated. For 2012 yields, varieties statistically equal to the top yielding variety are presented in bold type face. Coefficient of variation (CV) is also included in the tables. This is given as a general measurement of the precision of each experiment. Lower CV percentage values indicate less experimental variation and greater precision. CV values were not averaged across trials or

years. Wheat protein and hardness data are from composited samples, therefore no LSD or CV values are presented.

Cultivar choice should take into consideration as much performance data as possible with comparisons across years and locations. In addition to yield, end use quality, disease and insect resistance, lodging tendency, maturity, plant height, winter hardiness, test weight, and any observations from grower experience can be used in deciding on which cultivars to plant. The Idaho Wheat Commission website also provides a list of recommended varieties: [www.idahowheat.org](http://www.idahowheat.org) under “Preferred Varieties”.

### **Growing Conditions and Factors Affecting Trials**

Fall cereal trials were planted in October 2011. Winter wheat trial stands were well established at all locations. Winter temperatures across northern Idaho were mild and winter crop survived well. Late spring and early summer precipitation was above average in all locations, but late the summer was dry and conditions remained dry well into fall planting. *Cepheosporium* Stripe was observed in winter wheat in both re-cropped fields and fields with a three-year rotation including legumes. Stripe-rust occurred in low to moderate levels across the Palouse and Camas Prairies in mid to late summer of 2012. Late summer hail storms severely damaged enough acres in Nez Perce County to gain a county disaster designation in early July. The average winter wheat yield over all locations in 2011-2012 was 3 bushels/acre less than the average yield over the previous 3 crop years.

Spring trials were seeded between April 15 and May 14, 2012 (see Table 1). Frequent weather systems brought cool temperatures and precipitation throughout the planting season. Spring wheat yields in 2012 were 17 bushels/acre higher than the previous 3-year average. Spring barley yields were 15 bushels/acre higher than the previous 3-year average. Specific management practices for individual trials are listed in Table 1.

## Trial Locations, Management and Varieties Tested
